

L14: Pose SLAM and Point Cloud registration

* Summary of L13 ISAM

Cholesky $A^T A = \Lambda = R^T R$, R upper triangular

solve: $Ry = A^T b$ $\left\{ \begin{array}{l} \text{backsubstitution} \\ R^T S = y \end{array} \right.$ forward substitution.

QR

$$Q^T A = \begin{bmatrix} R \\ 0 \end{bmatrix}, \quad \text{solve } R S = d$$

Schur: Λ_m is diagonal \Rightarrow easy to invert.

Eliminate all dependence from landmarks and then Cholesky.

Ordering of the graph for variable elimination (colperm, coland)

Incremental update of R (iSAM)

* Data Association in ISAM

Given the full trajectory, DA allows for easy correspondences over time $C_{0:t}$, while EKF "trust" filter to only the cur correspondences C_t

Grouping landmarks, undoing wrong correspondences, etc. implies a change on A .

Grouping landmarks by a likelihood test \rightarrow greedy but tractable.

$$\Delta_{j,k} = \begin{bmatrix} m_k - m_j \\ m_j - m_k \end{bmatrix}$$

$$\| \Delta_{j,k} \|_{\Sigma_{j,k}}^2 < \chi_{d,\alpha}^2 \quad \left(\begin{array}{l} d=4 \\ \alpha = \text{confidence interval} \end{array} \right)$$

Other alternatives might work, like conditioning the joint Gaussian. Open problem.

We need the posterior covariance Σ_t , and from there marginalize everything except j, k landmarks.

Ex. 1d

if they are the same landmark Δ_m should be small.

* Covariance in JSAM

$$\Sigma = \Lambda^{-1} \quad (\Lambda \text{ is sparse but inverting is not efficient})$$

idea: No need to invert Λ , we have R .

$$\Lambda = A^T A = R^T R = \Sigma^{-1}$$

$$\Rightarrow R^T R \cdot \Sigma = I$$

$$\begin{cases} R^T \cdot Y = I \\ R \cdot \Sigma = Y \end{cases}$$

2 backsubstitutions, now of a matrix (set of vectors)

* bandwidth elimination

$$A = \begin{bmatrix} x_0 & x_1 & x_2 & x_3 & m_1 & m_2 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

Eliminate m_1 , will ~~in~~ add more factors to substitute the previous factors to m_1 .

$$A = \begin{bmatrix} \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

new "observation" relating x_0, x_1 through the removed m_1

eliminate m_2

$$\Lambda = \begin{bmatrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{bmatrix} = A^T A.$$

all landmarks eliminated, but new (equivalent) factors have appeared to express the same relations

* Relation to the Schur complement.

$$\Lambda = A^T A = \begin{bmatrix} \Lambda_x & \Lambda_{xm} \\ \Lambda_{mx} & \Lambda_m \end{bmatrix}$$

$$d_x = \begin{bmatrix} d_x \\ d_m \end{bmatrix},$$

$$A^T b = \begin{bmatrix} b_x \\ b_m \end{bmatrix}$$

$$(\Lambda_x - \Lambda_{xm} \Lambda_m^{-1} \Lambda_{mx}) d_x = b_x - \Lambda_{xm} \Lambda_m^{-1} b_m$$

the Schur complement is equivalent to eliminate (marginalize) all landmarks in the information matrix. These new factors are a new way to express the marginalization.

* Pose SLAM : only poses are estimated

factors (observations):

- Odometry
- Relative pose observations or loop closure.

$$h(i, j) = x_j - x_i$$

"from pose i we observe j "

$$A = \begin{bmatrix} 0 & 1 & 2 & 3 & 4 & 5 & 6 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \end{bmatrix}$$

} odom
} obs.

$H_k^j = I$ $H_k^i = -I$

how to generate observations between poses??

$$h(i, j) = x_j - x_i$$

- 1) Pose SLAM from landmark marginalization (not practical)
- 2) Virtual observation between poses: In general a Registration problem.

* Point Cloud Registration

PC here can be 3D or 2D, set of points

Ex:

$$Z_i = \{p_1, p_2, \dots, p_K\}$$

points from sensor (range-finder)
observed at pose x_i .

Problem: find the transformation from a pair of poses x_i, x_j , such that (homogeneous coord)

$$\boxed{{}^jT_i Z_i = Z_j} \quad \text{for all points in } Z.$$

Called registration, alignment, scanmatching. (2D)

Now, this definition considers 2 unrealistic things:

1- point to point correspondences is correct.

2- we sample the same points from x_i and x_j

* SVD methods (Arum'87)

If we have enough points, we can assume true the previous considerations

then, we define a cost function to minimize.

$$J(Z_i, Z_j) = \sum_k \|Z_j^k - {}^jT_i Z_i^k\|^2$$

the solution is found by decoupling Translation and Rotation:

$$t_i + \cancel{E} \{ z_i \} = E \{ z_j \} \quad (\text{same centroids translated.})$$

and then apply an SVD solution. of a cost term

$$\sum z_i, z_j.$$

Only 2 points in 2D
3 points in 3D.

Drawbacks:

sensitive to outliers

requires known correspondences

* RAUSAC (Fischler '81)

↳ Random sample consensus (General alg. for param. estimation).

We reject/eliminate outliers by sampling a subset of observation correspondences z_j^i, z_i^i minimal for solving:

- SVD representation $(z_j^i, z_i^i) = {}^i T_i^j$ solve the regression,

- ~~J~~ $J(z_i, z_j, {}^i T_i^j)$ test the hypothesis.

create a consensus set

* Iterative closest point (ICP)

given two point clouds, z_i, z_j with no a priori correspondences.

1) find closest points

$$d(p_i, z_j) = \min_{p_{z_j} \in z_j} \|p_{z_j} - p_i\| \quad , \quad p_i \in z_i \\ (p_i \in T_i z_i)$$

Brute force search of a single point vs all the other points. (Kd-tree)

2) Align the pointcloud z_j and $\{p_i\}$ with correspondences.

3) Do while convergence.

Ex:

Of course there will be outliers but iteratively we get rid of them.

SVD techniques are not the most convenient. \Rightarrow

Gradient based techniques work best.

$${}^jT_i := {}^jT_i^0 \oplus \nabla_T J(z_i, z_j)$$

(next Prob Rob ch 9)
